Funding for Yale Cancer Answers is provided by Smilow Cancer Hospital.

Welcome to Yale Cancer answers with your host doctor in East JGP are Yale Cancer answers features the latest information on cancer care by welcoming oncologists and specialists who are on the forefront of the battle to fight cancer this week.

It’s a conversation about the molecular mechanisms of cancer with Doctor Daryl Klein. Doctor Klein is an assistant professor of pharmacology at the Yale School of Medicine, where Doctor Chad Power as a
professor of surgical oncology.

So Darrell maybe we can start off by you telling us a little bit more about yourself and what it is exactly that you do.

Yeah, I mean I think. My path to become a medical researcher involves my personal back story and my love of competition. In some ways, I feel like I've been destined to study kinases and cancer and their mechanisms and and with the hope of developing useful cancer therapeutics. And my career trajectory if you will.

As a medical scientist, began long before my formal training.
I grew up in New Jersey just outside of Philadelphia, and at a young age, my sister was diagnosed with MEL or chronic myeloid leukemia. It’s a blood cancer that’s rare in children at that time. Over 40 years ago now, Peter Noel at the University of Pennsylvania in Philadelphia was studying the driving mutations that lead to CML. And he discovered a chromosome alteration that he dubbed the Philadelphia chromosome and MEL patients, like my sister and the results.
00:01:49.838 --> 00:01:50.858 of that change.
NOTE Confidence: 0.737310321

00:01:50.860 --> 00:01:53.479 Is that a new protein is made a fusion
NOTE Confidence: 0.737310321

00:01:53.479 --> 00:01:56.398 of a tyrosine kinase signaling protein?
NOTE Confidence: 0.737310321

00:01:56.400 --> 00:01:58.696 That’s that’s stuck in the on position,
NOTE Confidence: 0.737310321

00:01:58.700 --> 00:02:00.780 and that instructs cells to.
NOTE Confidence: 0.737310321

00:02:00.780 --> 00:02:03.867 To divide and grow and thus cancer.
NOTE Confidence: 0.737310321

00:02:03.870 --> 00:02:06.110 And that protein became a target for
NOTE Confidence: 0.737310321

00:02:06.110 --> 00:02:08.179 drug discovery and it really heralded
NOTE Confidence: 0.737310321

00:02:08.180 --> 00:02:10.664 the era of precision medicine that
NOTE Confidence: 0.737310321

00:02:10.664 --> 00:02:12.860 is specifically targeting a single.
NOTE Confidence: 0.737310321

00:02:12.860 --> 00:02:15.004 You know bad protein with a drug and
NOTE Confidence: 0.737310321

00:02:15.004 --> 00:02:17.099 that and that was really exciting.
NOTE Confidence: 0.737310321

00:02:17.100 --> 00:02:20.430 And in 2001 there was this huge success with.
NOTE Confidence: 0.737310321

00:02:20.430 --> 00:02:22.490 The mat neighbor or Gleevec,
NOTE Confidence: 0.737310321

00:02:22.490 --> 00:02:24.668 and that became the first drug
NOTE Confidence: 0.737310321

00:02:24.670 --> 00:02:26.386 that was developed to target a
specific kinase to treat a disease, and in this case, someone. 
And patients treated with this drug can live long lives with controlled disease.
Unfortunately for you know, Kimberly, it was just the beginning of understanding this disease.
And there were no therapeutics, and that meant you know, little could be done, and.
In this powerlessness drives me to find ways to spare other families similar devastation and to better understand cancer.
You know.
I really have spent a large part of my career investigating the molecular basis for oncogenic signaling. And you know on that path I attended the University of Pennsylvania for my undergrad in my PhD, and I did clinical rotations at the Children’s Hospital of Philadelphia Chop. So I was walking the same halls as Peter, Noel and my parents and my sister years before. I joined the MSTP or medical scientist training program and. This was funded by the NIH.
the National Institutes of Health, to grant to train a group of physicians, also to be researchers, and the goal of that program is basically to link basic science findings to the clinic. The bench to the bedside and to Brig lab progress into useful therapeutics as rapidly as possible. And I think the success of Leave Act was just the beginning of targeting kinases. These these tires and kinases other kinases and cancer. And so when I was at Penn, I studied under Professor Mark Lemon.
He was working on those other kinases that lead to different cancers.

And you know, to see how they might cause cancer and how we might leverage understanding their mechanisms to develop new therapeutics.

I also mentioned you know my my desire for you know competition. And I, you know, I grew up playing sports in college and I love competing and track and field and crew and football and baseball.
00:04:46.397 --> 00:04:48.056 lab at Penn and and was first

00:04:48.056 --> 00:04:49.199 introduced to lab research,

00:04:49.200 --> 00:04:51.408 I realized there that.

00:04:51.410 --> 00:04:53.246 Scientific researches is intensely

00:04:53.246 --> 00:04:56.467 competitive and I think it makes Olympic

00:04:56.467 --> 00:04:59.255 sport seem safe by comparison and and I

00:04:59.255 --> 00:05:02.500 love that and I loved everything about that.

00:05:02.500 --> 00:05:04.852 And then the problem is in

00:05:04.852 --> 00:05:06.028 sensually in science.

00:05:06.030 --> 00:05:08.042 You’re competing with unknown

00:05:08.042 --> 00:05:11.060 competitors and and an unknown number

00:05:11.142 --> 00:05:13.685 of of teams and and the rules of the

00:05:13.685 --> 00:05:15.957 game are undefined and you don’t even

00:05:15.957 --> 00:05:17.937 know when the conversation started.

00:05:17.940 --> 00:05:18.302 So,
and certainly your competitors have more money and resources than you do, so you’re always the underdog and that excites me and I like that.

When we started the project we were certain that half a dozen other groups in the world were already working on it and we didn’t know how far along they were. I once spent 50 hours straight in the lab when I was a grad student without sleeping.
And then you know that was exciting to me.

That’s something you can’t do in sport after the game you go home, but science is a years long competition with no timeouts and the intensity is off the charts so.

I think that frames kind of why I became a medical researcher and why I love doing the work that I do.

So let’s take a step back for a bit. I mean, that sounds really inspiring and interesting in terms of how this kind of came full circle.

How you? Had this experience?
with your sister and then went on to become a scientist that’s hopefully making a difference in the lives of other patients like her. But for our audience, I mean I should also mention that while I trained as an MDP MD PhD physician scientist, I’ve actually chosen a path devoted entirely to research. So during training, when I you know, find myself engaging with patients...
and talking to them about the unfortunately limited treatment options. I found that difficult and frustrating, and all I wanted to do was rush back to the lab and find new potential therapeutic avenues.

So I made a choice to devote myself entirely to lab work, but at the same time I'm still working with other physicians, scientists and clinicians to help bridge our discoveries. To the bedside.

Kinases are often drivers of cancers and the one that I've
been working on recently ALK and

a plastic lymphoma kinases is a
cancer related protein.

And much like the protein involved
in my sisters of Mle,
it's a tyrosine kinase and
basically tyrosine kinases instruct
the cells to grow and divide,
and if this is unregulated
that leads to cancer.
So ALK well, unlike the Siml case, ALK is.
Is A is a receptor tyrosine kinase.
So what that means is ALK is
located in a different part of
the cell than the CML kinase.
So if it if a cell were an ocean,
the CML kinase would be a submarine and ALK would be more like an aircraft carrier at the surface and so this. Localization difference has therapeutic implications. As you might imagine, you can’t target a submarine the same way you would target in an aircraft carrier. So in the clinic we use small molecule. You know missile like drugs that can dive deep into the ocean to reach that kinase whereas for ALK we have an opportunity to use antibodies that can target it at the cell surface, so more like a.
You know a B52 bomber. It's been known for years that ALK is a driver of neuroblastoma. Now neuroblastoma is a cancer of the peripheral nervous system. It's one of the more common pediatric cancers that accounts for more than 10% of childhood cancer mortality. But clinically useful therapeutics have been slow to develop, and I think you know one of the key reasons for this slow development of treatments is likely the lack of a structural framework for the target alcc. Simply put, we have you know no idea what it
looked like or how it functioned.

It was a complete mystery before our work. I mean the fact that ALK is expressed on neuroblastoma cells but is not present. On healthy tissue makes Alka veritable oncogenic beacon. That’s a perfect target for precision medicine.

In each case the protein. Specifically, if you’re targeting the protein specifically, it should have little side effects outside of the cancer itself.
And the hope is that if we can target this kinase alken neuroblastoma. That we might have the same positive outcomes for neuroblastoma that we see for patients with KMLE.

So you know one of the things that always fascinates me is how you find these things to begin with. I mean, how do we know that these kinases play a role in cancer? How does that? How do you figure that out? How do you know which kinases are submarines and which kinases are our aircraft carriers, I mean.

And how did you figure out that these were important anyways?
How does that happen?

That’s a good question.

That’s certainly outside of my lab’s expertise.

A lot of that is done through genomic work and associating certain genes with certain disease phenotypes, and so where my lab’s expertise comes in pretty much after the fact. Once these associations are known, that’s where we come in to help define bio physically and structurally, exactly how these kinases and uncle genes are acting, and hopefully if we have a molecular
picture of that how we might design
and develop therapeutics to.
To stall that and and prevent disease.
So when you say that it kind of all
starts with understanding what genes
are expressed in what genes aren’t.
I mean it, it sounds like the progress
that we make in terms of cancer
is really investigators.
Building on other investigators
build on other investigators work.
So somebody you know maybe was sequencing
some genes and found that some genes were
overexpressed in some cancers versus not.
And then other people kind of discovered that
that gene was associated with a protein like.
A kinase and then you look at that kinase and say well where is it and how can we target it? Is that kind of how that works? That's exactly right, right? I mean, it's work of a tremendous number of individuals with differing expertise. Certainly the approach my lab takes is just one cog in that machine, one that is keenly important to understand the mechanism of how molecules work,
which can then give us insight into how we might target these and develop therapeutics.

And then the other question that I often have is. OK, so you know you discover this kinase and you discover that it’s important in cancer. Why is it that some kinases are important in some cancers but not in others? Why? Why do you have these genes for these kinases to begin with? And why are they differentially expressed? Cancer often recapitulates the paradigms and during development.
So all of these kinases are crucially important in the stages of development and help patterning and complex tissues. After that, they aren't used so much in adulthood, and it's only during cancer that a lot of these developmental pathways are reawakened, and they can be reawakened in different tissues and different places, but they all lead to the same thing. Basically once you turn a kinase on, the growth instructions and
when that’s not counterbalanced, that’s how cancer develops. Well, we’re going to take a short break for a medical minute, but when we come back, let’s learn more about the molecular mechanisms of cancer and how exactly we target these differentially expressed kinases to actually make a difference for patients, please stay tuned for more with my guest doctor Daryl Klein. funding for Yale Cancer Answers comes from Smilow Cancer Hospital with an event focused on nutrition for cancer survivorship presented by the Smilow
Cancer Care Center in Trumbull.
April 14th Register at Yale Cancer Center.
Org or email cancer answers at Yale.
The American Cancer Society estimates that nearly 150,000 people in the US will be diagnosed with colorectal cancer this year alone. When detected, early colorectal cancer is easily treated and highly curable, and men and women over the age of 45 should have regular colonoscopies to screen for the disease. Patients with colorectal cancer have more hope than ever before, thanks to increased access to advanced
therapies and specialized care. Clinical trials are currently underway at federally designated Comprehensive Cancer Centers. Such as Yale Cancer Center and its Milo Cancer Hospital to test innovative new treatments for colorectal cancer tumor. Gene analysis has helped improve management of colorectal cancer by identifying the patients most likely to benefit from chemotherapy and newer targeted agents, resulting in more patient specific treatment. More information is available at yalecancercenter.org.
Welcome back to Yale Cancer answers. This is doctor in East Egg part and I’m joined tonight by my guest doctor, Daryl Klein. We’re learning more about the molecular mechanisms of cancer and right before the break Daryl was telling us about this profoundly inspiring story of his sister who is diagnosed with CML, which really started his journey on becoming a physician scientist, and one who is particularly interested in these molecules called kinases, which really work. To activate the growth of cancer.
cells and so you know Darrell before the break you were mentioning that eurolab really after we know that you know a kinase is involved in a particular cancer is really involved in looking at its structure and kind of how to target it. Is that right? my lab is a structural biology lab, so you know, we’re sensually photographers. But we take pictures of of very, very tiny things, molecules and proteins, and so this. Requires specialized equipment cameras if you will. That use X rays and electrons rather...
than light in the visual spectrum that we’re used to. You know, many people know DNA, so let’s start there. People have heard of DNA and Watson and Crick and they’re double Helix. And DNA is basically a cookbook with 10s of thousands of recipes, and they’re mostly protein recipes, so I guess it’s a keto or Paleo cookbook. ALK is one of these recipes. And the recipe in the DNA cookbook tells us the ingredients and the order to make ALK. But one big problem with this DNA cookbook is it’s not illustrated, so I guess it’s a keto or Paleo cookbook.
so we have no idea what the final product will look like.

So you know my lab follows the recipe to take pictures of the final products to illustrate this, this DNA cookbook.

So we take molecular photographs of the protein and also the mutants that are found in cancer. And in these pictures give us a better understanding of how things supposed to look like and how it changes in cancer. And in this can inform us about approaches to designing targeted therapeutics.

So my lab just reported the structure of the protein ALK in nature.
That’s the tyrosine kinase that’s important in neuroblastoma. And this gave us a first look at this unique uncle Gene and it’s, you know it’s going to be impossible for me to relay the complexities here. But if we stick to our Analogy of the the cell is an ocean, it’s. It’s not unreasonable to say that Alcc did actually look a bit like an aircraft carrier. I mean it had this. Unusual a long gated structure and it probably lies parallel to the to the surface, so it’s like an aircraft carrier floating on the water.
Or the surface of a cell.

And and furthermore, we can see how it actually gets activated. Basically two of these aircraft carriers line up next to one another and in that position they’re then capable to sell to send their their growth signals, which ultimately end up being cancerous growth signals. To the neuroblastoma cell. Uncontrolled ALK activation like this leads to cancer and it and it results from the tumor continuing to express this developmental out gene along with its stimulatory ligand. Our research reveals an approach
00:20:26.090 --> 00:20:29.229 to shutting off ALK and and that
00:20:29.229 --> 00:20:31.484 it can be quite straightforward.
00:20:31.490 --> 00:20:34.550 Potentially if we use our structure
00:20:34.550 --> 00:20:35.790 as a as a blueprint,
00:20:35.790 --> 00:20:37.536 we can see clear areas where
00:20:37.536 --> 00:20:39.550 we would want to target this.
00:20:39.550 --> 00:20:41.470 This aircraft like molecule.
00:20:41.470 --> 00:20:43.731 I mean there’s certain vulnerabilities
00:20:43.731 --> 00:20:46.118 that are revealed in the structure that
00:20:46.118 --> 00:20:48.283 we can strategically target and and
00:20:48.283 --> 00:20:50.425 you know sync this aircraft carrier,
00:20:50.425 --> 00:20:53.310 and so my lab now is designing potent
00:20:53.310 --> 00:20:54.924 antibodies. That specifically
00:20:54.924 --> 00:20:57.614 target these regions in ALK,
molecules currently out there in use for Neuroblastoma, as well as many other different cancers that are driven or partially dependent on kinases. And compared to small molecule therapeutics antibodies, I think can offer a great benefit. The small molecule drugs that are now currently in use like prison and learn Latin. They target the intracellular. The actual kinase domain of the protein out. And one problem with these types of inhibitors is that you can’t keep fooling the cancer for very long. They the cancer figures out this
trip quite fast that you're trying to inhibit it in this domain, and the cancer makes changes that diminish the drugs impact. Whereas I think the antibody approach is a more brute force approach and it’s harder for the cancer to overcome this, the strategy of inhibition. I think the therapeutic future will likely use a combination of these two to completely dismantle the machinery. In some ways you know cancer can be viewed as having some of the...
similar challenges that we see for SARS, CoV2 and both use similar strategies to overcome disease. Both you know cancer and viruses mutate rapidly. And they can evolve to different inhibitor approaches. And just as we use antibodies through vaccination or or directly injecting recombinant antibodies and small molecules to overcome COVID. Now we have a new blueprint for ALK to help us overcome similar challenges that are encountered in in cancer and in particular neuroblastoma. And it sounds like when you know the the
structure of these aircraft carriers. But you can be very specific about targeting those particular molecules as opposed to normal cells. So you might have you know a bomber that only targets, a mechanism whereby these two aircraft carriers can’t line up together that really wouldn’t apply in any other situation, and you can try to get more precise or more targeted therapies. Is that right?
That's exactly right, and remember that I said that you know, since alpha is expressed only on neuroblastoma cells but not present on healthy tissue, it really makes targeting ALK the perfect for you know. Set up for precision medicine and then a layer on top of that, which I think you were just referring to is now that we know the detailed structure and blueprints of this. And that's exactly what we're trying to do. We're trying to design antibodies that specifically block areas on the protein that are
involved in important for it’s activation.

That is precisely where the ligand binds to activate the receptor and getting back to how it’s activated.

Where we see the the two molecules lining up side-by-side to each other,

we’re designing antibodies that can block that interface to prevent it from being activated independent of ligand.

Which could be caused by certain mutations,

which is further research that we’re doing now or or with the ligand.

So we’re using all this information to specifically design antibodies
that are tailored to this molecule and the type of mutations or mechanisms that activate it specifically in neuroblastoma.

And so as you design these antibodies in these treatments, you’re doing that in the lab. How does it actually get into patients? How does it affect people like your sister? Because that’s where the story really started and how long does that whole process take? You’re right, that’s a that’s certainly a long process and you know Cancer Research is so matured and specialized now that it really requires
you know effort to put these discoveries into usable formats and for others to build upon and meaningful ways.

And just as the NIH created that MSTP program to link basic science and patient care now I think we need similar links between basic science researchers. I mean, the you know RNA biologist and chromosome researcher and. And in the biophysicist like me trying to link up with the model Organism biologist to test the a lot of these and preclinical setups. We all speak a different scientific dialect and we have different perspectives,
so you know how do we work together
and in one answer to that is is,
being part of the Yale Cancer Biology Institute that I'm a part of.
You know we really bring together desperate researchers among those interested in cancer.
And so you know now I have and and a cohort of people and colleagues that I can work with that can bring our developing antibodies into preclinical testing quite rapidly to see if they do. So good activity in vivo and then that hopefully can be rapidly leveraged
into reaching the patients that desperately need these treatments.

Sounds very much like you had mentioned earlier, but this is kind of a microcosm for the macrocosm of how science works, that your lab puts together. People who all kind of come at the problem of ALK from a slightly different vantage point. But the work in your lab kind of builds on the work of other people’s labs, and so maybe in the last few minutes that we have, you could tell us kind of a little bit about.
00:27:26.810 --> 00:27:29.357 How that works in the grand scheme of things?
NOTE Confidence: 0.90850388875
00:27:29.360 --> 00:27:31.150 I mean, it sounds like.
NOTE Confidence: 0.90850388875
00:27:31.150 --> 00:27:33.230 One of the things that we’ve realized with
NOTE Confidence: 0.90850388875
00:27:33.230 --> 00:27:35.266 the pandemic is that the world is shrinking,
NOTE Confidence: 0.90850388875
00:27:35.270 --> 00:27:38.015 and hopefully the scientific discovery
NOTE Confidence: 0.90850388875
00:27:38.015 --> 00:27:41.559 from one lab to another kind of.
NOTE Confidence: 0.90850388875
00:27:41.560 --> 00:27:43.240 Bounces around fairly easily.
NOTE Confidence: 0.90850388875
00:27:43.240 --> 00:27:45.340 How does that collaboration work?
NOTE Confidence: 0.882697558
00:27:46.130 --> 00:27:49.136 I think it is. It is certainly a challenge
NOTE Confidence: 0.882697558
00:27:49.136 --> 00:27:51.664 and I think you know getting getting
NOTE Confidence: 0.882697558
00:27:51.664 --> 00:27:54.656 researchers to to talk to each other and
NOTE Confidence: 0.882697558
00:27:54.656 --> 00:27:57.786 work together is an important part of that.
NOTE Confidence: 0.882697558
00:27:57.790 --> 00:28:00.940 And like you said, I think you know
NOTE Confidence: 0.882697558
00:28:00.940 --> 00:28:03.550 during the pandemic and having people
NOTE Confidence: 0.882697558
00:28:03.550 --> 00:28:06.008 communicate in different ways like we
NOTE Confidence: 0.882697558
00:28:06.008 --> 00:28:08.850 are now through zoom and other things.
Maybe the world is shrinking a bit and I think that’s a good thing for science and that’s a good thing for research because. Of course, all of us working independently and making advances. We don’t want them to go unnoticed by the people next in that chain that you were talking about. That’s necessary to make the leap to bring these discoveries to their therapeutic potential.

Doctor Daryl Klein is an assistant professor of pharmacology at the Yale School of Medicine. If you have questions,
00:28:40.852 --> 00:28:42.747 the address is canceranswers@yale.edu
NOTE Confidence: 0.772678952866667
00:28:42.747 --> 00:28:44.949 and past editions of the program
NOTE Confidence: 0.772678952866667
00:28:44.949 --> 00:28:47.028 are available in audio and written.
NOTE Confidence: 0.772678952866667
00:28:47.030 --> 00:28:48.968 Farm at yalecancercenter.org.
NOTE Confidence: 0.772678952866667
00:28:48.968 --> 00:28:51.512 We hope you’ll join us next week to
NOTE Confidence: 0.772678952866667
00:28:51.512 --> 00:28:53.449 learn more about the fight against
NOTE Confidence: 0.772678952866667
00:28:53.449 --> 00:28:55.014 cancer here on Connecticut Public
